INTRODUCTION

Over the past 81 years, Thermal Ceramics has proven itself to be a world leader in solving problems for heat-intensive industries.

The refractory ceramic fiber manufactured by Thermal Ceramics is a highly versatile material. It can be spun or blown into bulk, air-laid into a blanket, folded into modules, formed into monolithic modules (Pyro-Bloc), converted into boards and shapes, die-cut into gaskets, twisted into yarns, woven into rope and cloth, and blended into liquid binders for coatings and cements. With this wide range of products, Thermal Ceramics can provide exactly the right product, or engineered system to fit your requirements. Thermal Ceramics has an experienced staff of refractory specialists to assist you in product selection, system design, and installation techniques.

Thermal Ceramics has enjoyed great success with its ceramic fiber products due to their cost-effectiveness and excellent insulating properties. They are lightweight and have low thermal conductivities, excellent resistance to thermal shock, outstanding electrical resistivity, and good acoustical properties.

This Design and Installation Manual is intended to give the designers, installers, and users of Thermal Ceramics ceramic fiber products a broad range of information on how to select the most appropriate fiber system for a particular application, necessary design criteria, and how to correctly install the selected system.

PLEASE NOTE: This manual has been designed to easily accommodate new or revised information. Holders of the manual are advised to keep their address current with the Advertising and Sales Promotion Department at Thermal Ceramics in Augusta, Georgia. Any questions or comments regarding this manual should be addressed to your local Thermal Ceramics representative.

PYRO-BLOC M MODULE

The Pyro-Bloc M Module is a monolithic edge-grain ceramic fiber module designed for industrial furnaces that require corrosion barriers, a back-up blanket layer, or a pre-laid-out stud system.

The Pyro-Bloc M Module is a unique module composed of two monolithic pieces of edge-grain ceramic fiber (Pyro-Log®) with an internal M yoke and two support tubes. Pyro-Bloc M Modules are available in densities ranging from 10 - 15 pcf (160 - 240 kg/m³) and in thicknesses from 3 -12 inches (76 - 305 mm).

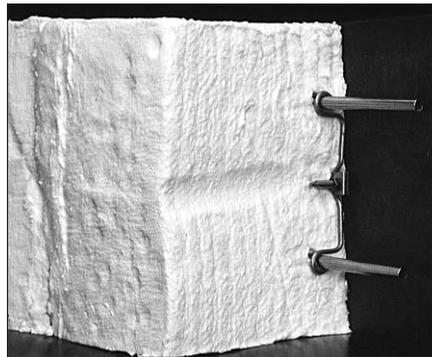

Figure 2 - Pyro-Bloc M Module Cutaway Displaying Internal Anchoring as well as Stud and Nut

The internal anchor hardware is made of 316SS, which offers better corrosion resistance than 304SS. Studs, nuts and installation tools are purchased separately.

The installation equipment and tools described in this manual have been developed to ensure a quick, reliable installation. In addition to simplifying the attachment of the modules, these installation tools allow you to achieve high degrees of compression between modules.

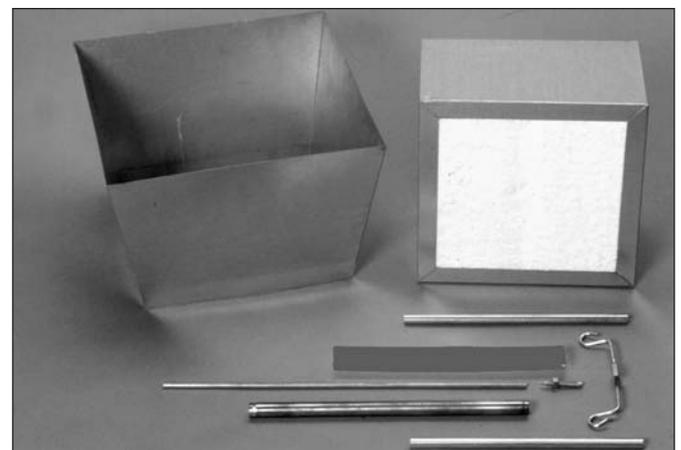

Figure 3 - Pyro-Bloc M Module with Anchor Hardware and Installation Equipment

1. GENERAL

1.1 Lining Considerations

A Pyro-Bloc M Module lining can be installed in a soldier course fashion on vertical walls with batten strip or in a parquet pattern on a roof. Figures 5 - 7 show how a typical Pyro-Bloc M Module lining would be installed on the walls and roof of a furnace.

Prior to installing the Pyro-Bloc M Modules, it is necessary to lay out the necessary stud pattern and weld the studs in place. At this point, a stalastic coating can be applied to the steel casing followed by a layer of blanket for back-up as well as a layer of stainless steel foil for a vapor barrier if required. The specific operating conditions for your particular furnace will determine the need for stalastic coatings, back-up blanket or vapor barriers.

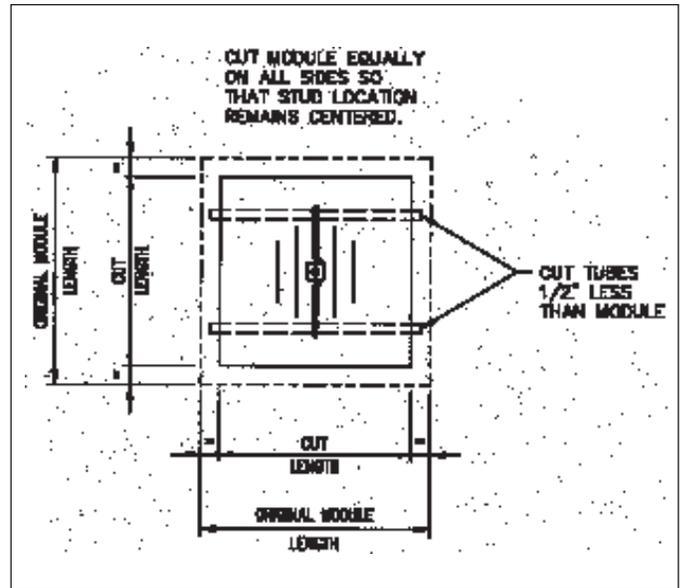

Figure 4 - Typical Module Cutting Detail

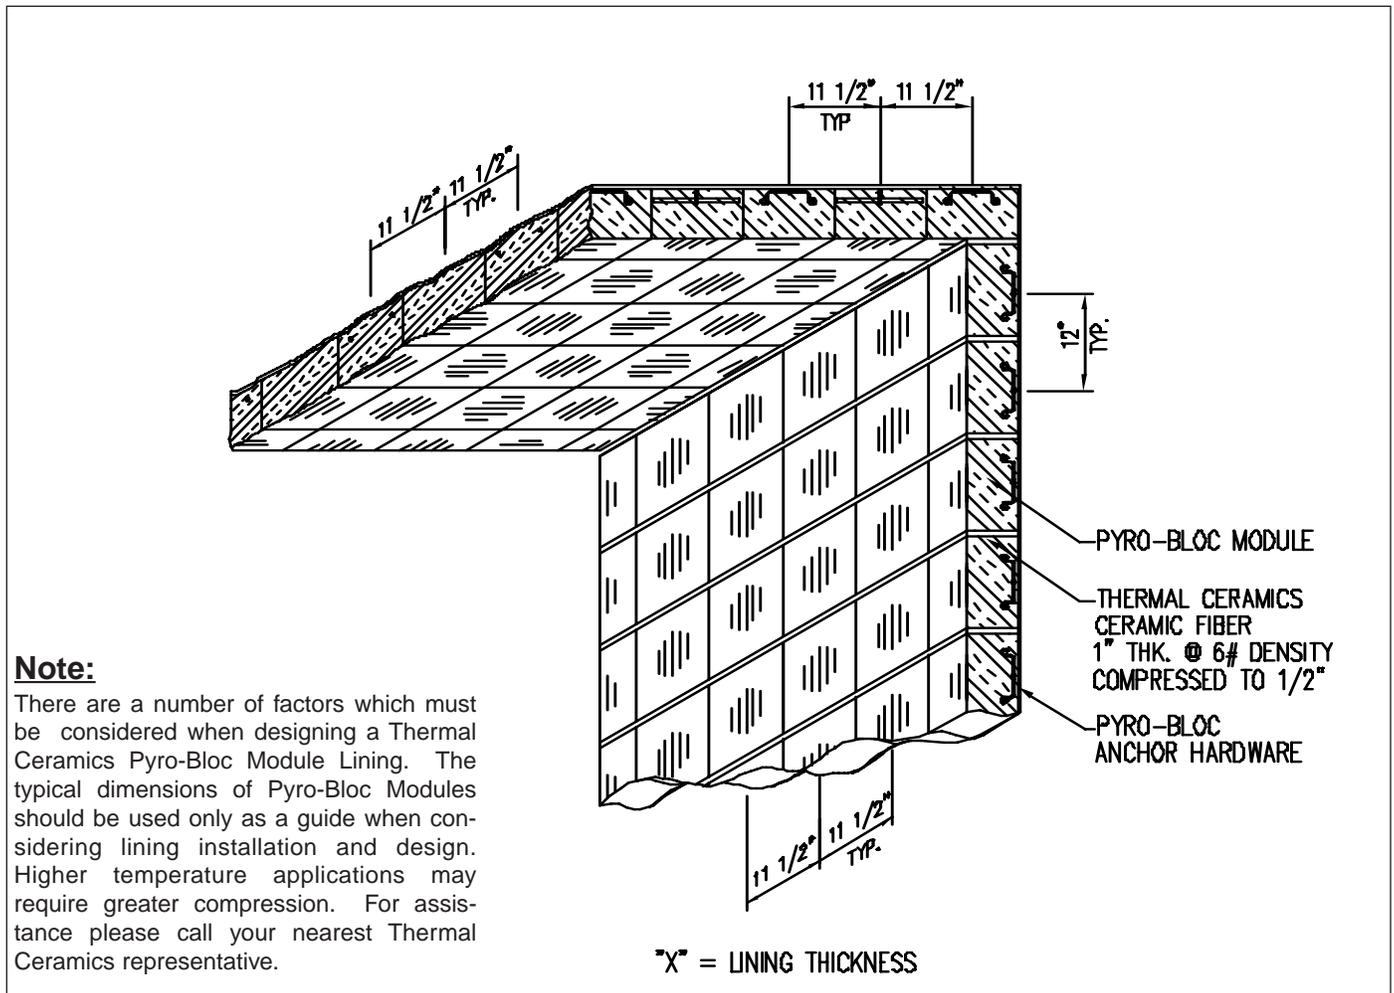

Figure 5 - Typical Pyro-Bloc M 12 x 12 Module Lining

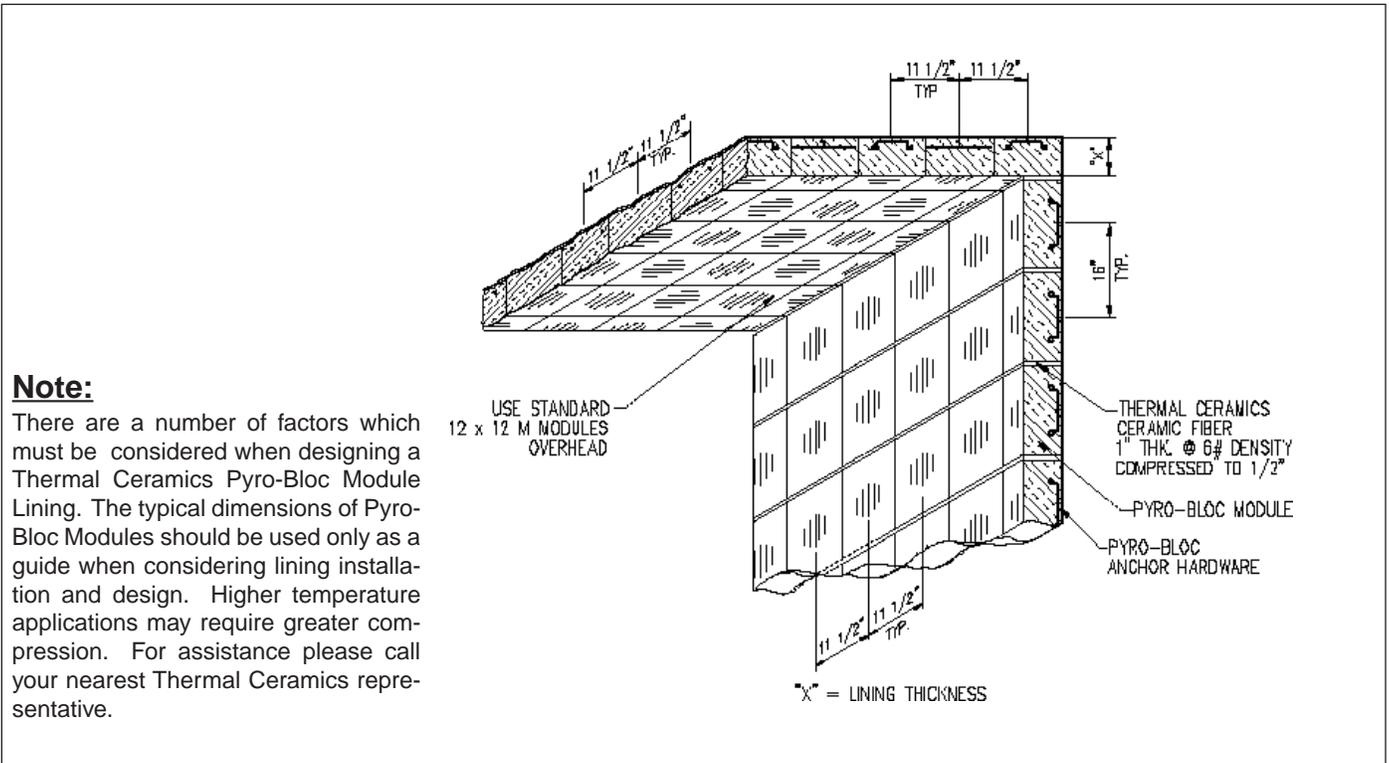

Figure 6 - Typical Pyro-Bloc M 12 x 16 Module Lining

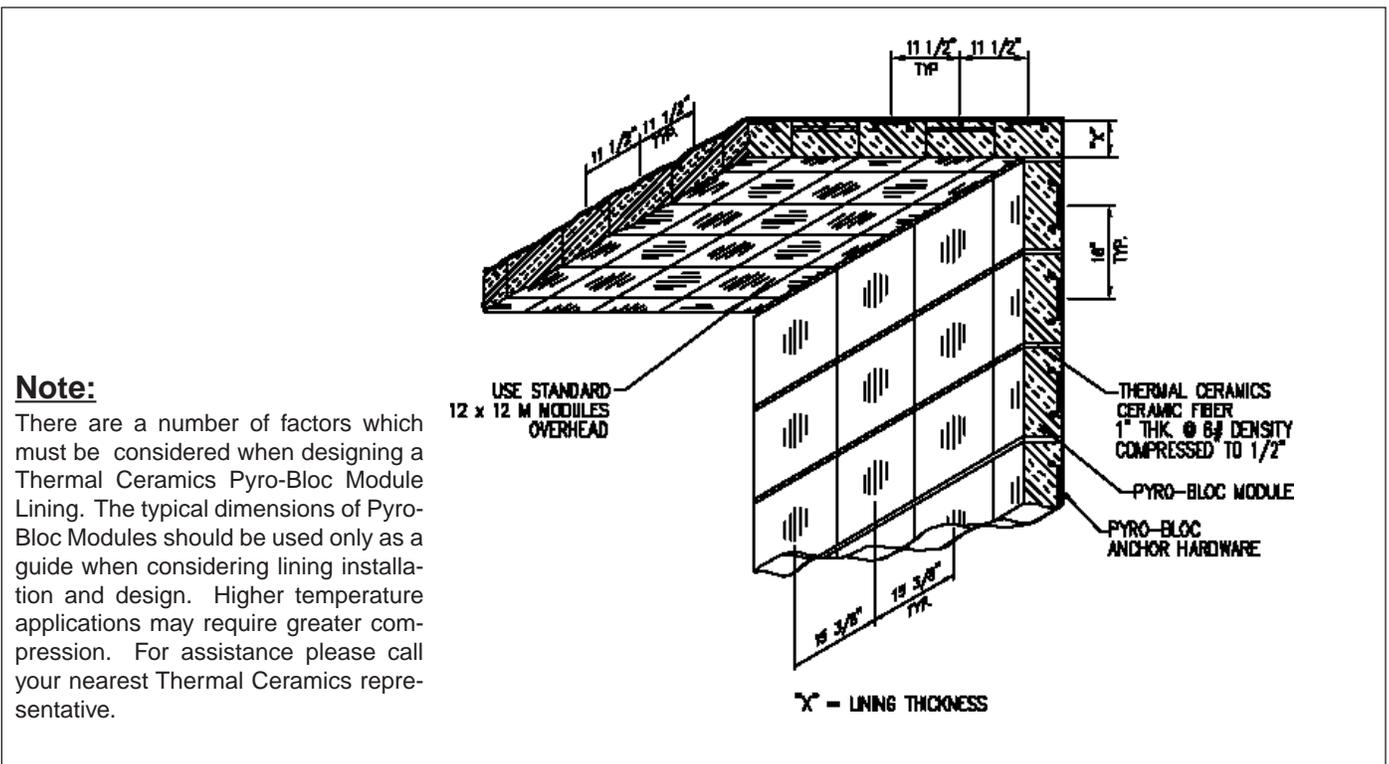

Figure 7 - Typical Pyro-Bloc M 16 x 16 Module Lining

Once the studs and back-up materials are in place, the Pyro-Bloc M Modules can be installed. The yoke in the Pyro-Bloc M Module has an offset to allow for the stud to be in the center of the module.

The Pyro-Bloc M Module is easy to cut or trim to allow for obstructions such as burners or peepsites. Best results will be achieved if the module is trimmed equally from opposite sides of the module, so that the stud will remain centered as closely as possible. This point is outlined in the cutting detail in Figure 5. It is best to cut less than what is necessary and compress the module into place to ensure the tightest possible joint.

Bullnose areas, which cause problems for other modular systems, are easily accommodated by the Pyro-Bloc Corner Bloc Module. These Pyro-Bloc Corner Bloc Modules can be installed using the same Pyro-Bloc M Module anchor hardware. Alternatively our Pyro-Bloc T-Bar anchoring system can be used where access is limited. Figures 8 and 9 illustrate these two Pyro-Bloc Corner Bloc anchoring options.

1.2 Site Preparation

The steel surface to be lined should be free of heavy rust or scale, non-conductive paints, dried refractory cements or oil. Sandblasting, wire brushing or grinding will be required to clean the surface, or at least the area where the stud is to be attached.

Set up good scaffolding so there will be easy access to the areas to be lined. Also, make arrangements for the material to be as close to the work area as possible without being in the way, so it can be efficiently delivered to the work crews.

The steel shell should preferably be 10 gage or thicker (0.135" min.). This will minimize difficulty with blowing holes in the steel while trying to weld the studs in place.

1.3 Stud Welding

The process of arc stud welding involves the same principles as any other arc welding process. 1) Creation of welding heat by developing an arc between the stud and the plate. 2) Bringing the two pieces together when the proper temperature is reached.

The equipment needed includes a stud gun, a control unit and an adequate DC welding current supply. The stud is loaded into the properly sized chuck, the ceramic ferrule is placed in position over the end of the stud and the gun is properly positioned for welding. The gun, control unit and welding machine are connected as shown in Figure 10 or 11 for welding.

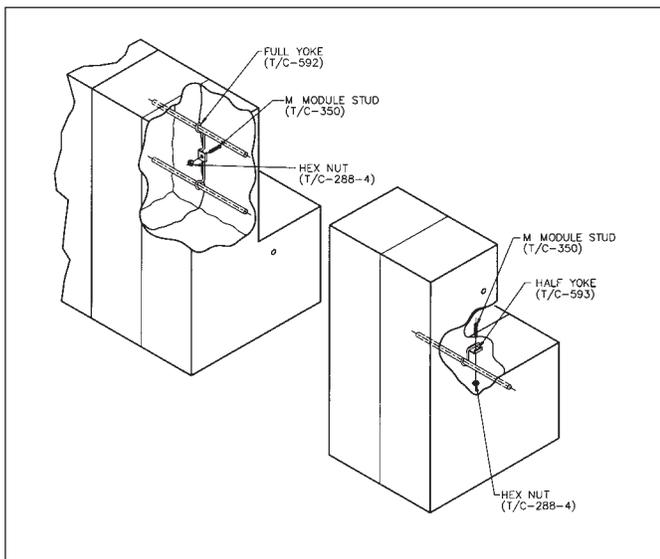

Figure 8 - Pyro-Bloc M Module Corner Bloc

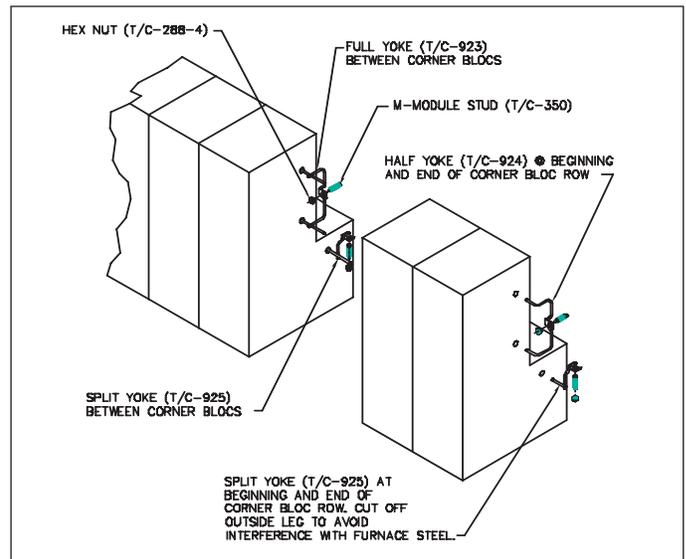

Figure 9 - Pyro-Bloc T-Bar Module Corner Bloc

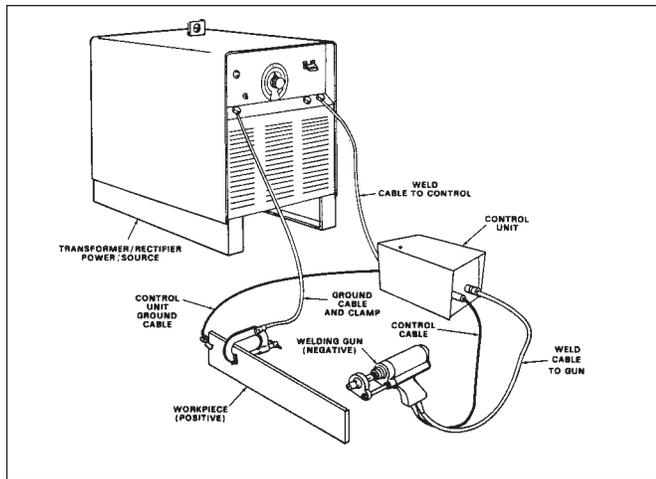

Figure 10 - Equipment Setup with Separate Power Source and Control Box

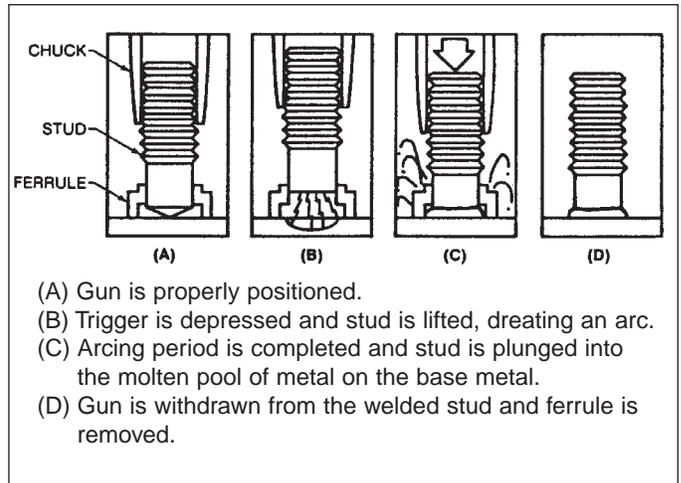

Figure 12 - The Welding Process

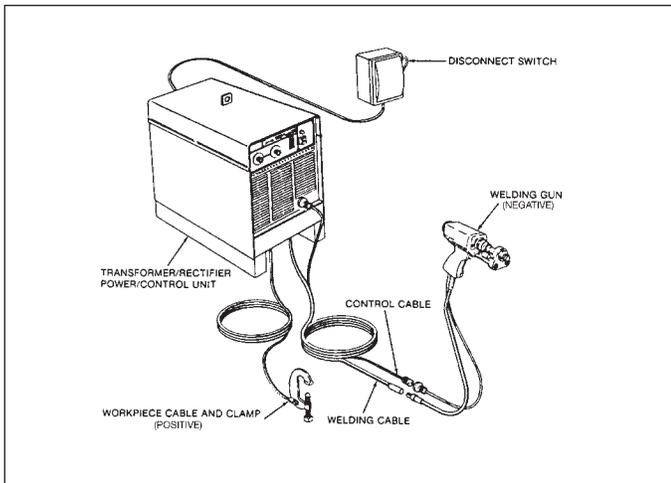

Figure 11 - Equipment Setup with Power Source and Control Box

The welding process is shown in Figure 12. A solenoid coil within the gun is energized when the trigger is pulled. This lifts the stud off the plate and creates an arc. The end of the stud and the plate are melted by the arc. Upon completion of the preset arc period, the welding current is automatically shut off. The mainspring within the gun then plunges the stud into the molten pool on the plate to complete the weld. The gun should then be lifted off the stud and the ferrule broken off.

Installation rates for welding studs in this manner will vary with the size of the stud and other working conditions. However, an average rate is approximately six studs per minute.

To set up the gun for shooting studs, set the plunge length to approximately 1/8" (3.2 mm) (Figure 13). The approximate settings for weld time and weld current is provided in Table 1.

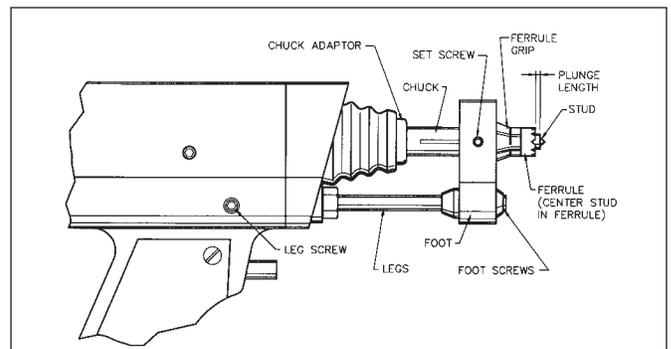

Figure 13 - Portable Stud Gun

Stud Weld Base Diameter (in.)	Stud Weld Base Diameter (mm)	Weld Time (Cycles)*	Weld Current (Amperes)
1/4	6.4	10	400
5/16	7.9	15	500
3/8	9.5	20	550
7/16	11.1	25	700
1/2	12.7	30	800

*60 cycles = 1 second

The above settings vary due to the power source condition of the work piece, age of equipment, length of cable used between power source and the control unit and the alloy to be used. After determination of proper settings, the unit is ready to weld studs.

Table 1 - Typical Welding Conditions for Stud Welding of Steel

2 INSTALLATION

The Pyro-Bloc M Modules are typically installed soldier course on walls with a batten strip between rows while a parquet pattern is used when installing on a roof (Figure 2). The Pyro-Bloc M Module requires a pre-layed-out stud pattern so the first step is to establish the layout.

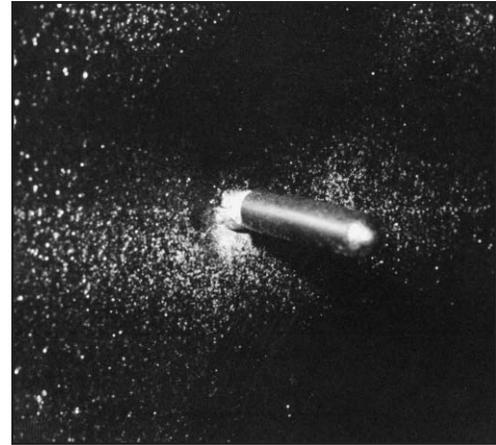

Step 1

Measure the correct distance vertically and horizontally and mark with a chalk line. Typically, for walls the stud spacing is 11½" (292mm) horizontally and 12" (305mm) vertically while on roofs the spacing will be 11½" x 11½" (292mm x 292mm).

Step 2

At the points where the chalk lines cross, weld an M Module two step stud onto the steel casing.

Step 3

Install the plastic covers over the studs and coat the steel casing with stalastic. If a coating is not being used, plastic covers for the studs are not needed. At this point, back-up layers of blanket and stainless steel foil vapor barriers should be installed if being incorporated into the lining of the furnace.

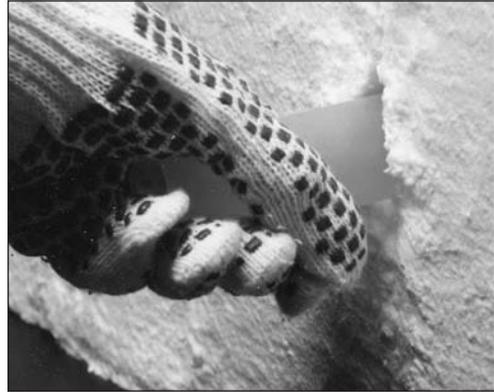

Step 4

The Pyro-Bloc M Modules can be installed. Insert the module (hot face side down) into a compression box using a compression funnel. In this way the Pyro-Bloc M Module is precompressed when it is installed.

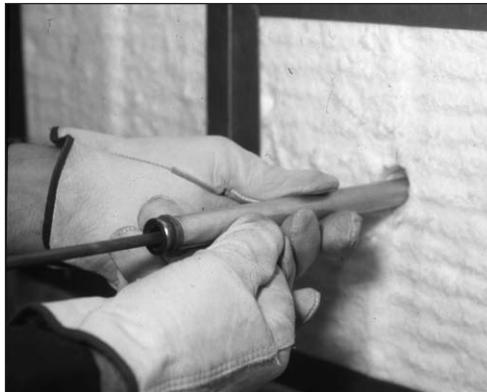

Step 5

Insert the guide rod through the hole in the yoke tab. Lift compression box with module and guide rod into position and thread the guide rod onto the small tip on the M Module stud. The module and compression box can now be pushed into place with the module yoke tab sliding onto the stud and against the steel casing.

Step 8

Remove the collapsible red access tube.

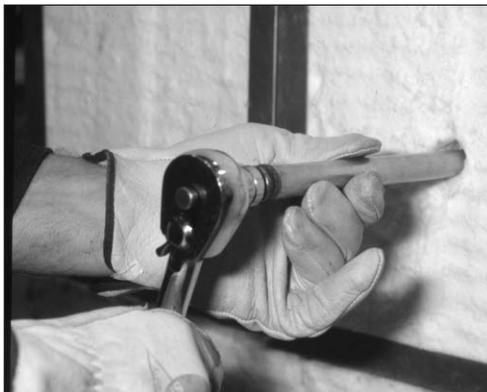

Step 6

Insert a hexnut into the end of the nut driver and slide onto the guide rod. Thread the nut by hand onto the stud. Remove the guide rod.

Step 9

Pinch the fiber closed over the stud to protect it from the heat.

Step 7

Using a ratchet or drill, tighten the nut onto the stud.

Step 10

After all the adjacent modules have been installed, you can remove the compression box.

Step 11

When all the Pyro-Bloc M Modules have been installed, the lining should be tamped out to further tighten all joints and close any gaps that may exist.

Notice:

Some of the products described in this literature contain Refractory Ceramic Fiber (RCF) and/or crystalline silica (cristobalite or quartz). Based on experimental animal data, the International Agency for Research on Cancer (IARC) has classified RCF, along with fibrous glasswool and mineral wool, as a possible human carcinogen (Group 2B) and respirable crystalline silica as a probable human carcinogen (Group 2A).

To reduce the potential risk of health effects, Thermal Ceramics recommends engineering controls and safe work practices be followed by product users. Contact the Thermal Ceramics Product Stewardship Group (1-800-722-5681) to request detailed information contained in its MSDSs and product literature and videos.

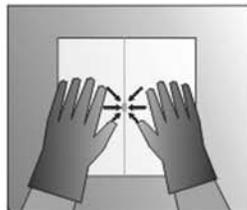

IMPORTANT INSTALLATION INFORMATION

Install Pyro-Bloc Modules in Accordance with the Installation Manuals
 Pyro-Bloc M Module - Installation Manual M #143 Issued 12/02 (or later)
 Pyro-Bloc Y Module - Installation Manual M #142 Issued 7/01 (or later)

After installation of the Module -
REMOVE TUBE

- Pyro-Bloc M Module - Red Plastic Access Tube
- Pyro-Bloc Y Module - Aluminum Tube

Close Tube Opening

Tamp Module in Accordance with
Appropriate Installation Manual.

Amorphous: Having no definite crystalline structure or form.

Back-up Insulating Material: The layer or layers of insulating material that are located between the hot face insulating layer and the outer casing.

Blanket: A flexible unbonded ceramic fibrous insulating material of reasonably determinate dimensions.

Board: A substantially rigid or semi-rigid flat sheet produced by vacuum forming.

Bulk Fiber: Ceramic fibers in the "as-produced" state.

Butt Joint: A ceramic fiber wallpaper construction joint where edges of adjacent blankets meet.

Cold Face Temperature: Term used to denote the outside casing temperature.

Continuous Use Limit: Long-term (continuous) temperature limit for a product installed as a lining. This temperature is based upon product shrinkage, specifically what is considered to be a "manageable" or "controllable" shrinkage. This term is not to be confused with temperature rating.

Cristobalite: A crystalline phase of silica which will begin to form above 1800°F.

Devitrification: The phase transformation from glass to crystalline structure.

Edge-grain: The orientation of a fiber system in which strips of ceramic fiber blanket or felt are oriented perpendicular to the plane of the furnace casing.

Felt (Pressed): A flexible sheet product formed from ceramic fibers and bonded with an organic binder.

Heat Loss: The term used to denote the amount of heat being lost through a lining construction over time, measured in BTU/sq ft/min, (watts/sq in).

Heat Storage: The thermal property of a material wherein heat accumulates in the mass (which in refractories is a function primarily of the material's specific heat, mass, and temperature rise measured in Btu/lb°F (Cal/g°C)).

Heat Transfer: The study of heat flow mechanisms - conduction, convection, and radiation.

High Alumina Fiber: A ceramic fiber containing more than 90% alumina, giving a high use limit. Mullite fiber is also used in high temperature applications.

High Purity (HP) Fiber: A ceramic fiber produced from synthetic alumina and silica.

Hot Face Insulating Material: The layer of lining insulating material that has at least one surface exposed to the full temperature of the furnace gases.

Kaolin Fiber: A ceramic fiber produced from calcined kaolin.

Laminar Flow: The flow of a gas in which the gas stream moves in straight lines parallel to the direction of the flow.

Layered Lining Wallpaper: Lining that is composed of several layers and thicknesses of refractory ceramic fiber.

Linear Shrinkage: The amount of shrinkage which occurs along the length of a material after it has been subjected to elevated temperatures and then cooled - measured in percent of original fired length.

Lock Washers: Washers used in conjunction with Kao-Lok studs. They are slotted so that when pushed over the stud and then twisted 90° the washer is locked into place, other locking systems are available, such as cone anchors. Lock anchors come in ceramics or alloy metals to suit temperature requirements.

Maximum Temperature Rating: The temperature which is used by the industry as a loose classification of different grades of ceramic fiber. This is generally higher than the continuous use limit.

Module: A prefabricated unit which can be applied as a lining block to the inner face of a furnace structure.

Mortar/Cement: A ceramic-based adhesive for attaching ceramic fiber products to other surfaces.

Mullite: A crystalline phase of alumina-silica.

Overlap Construction: A construction technique used to accommodate shrinkage in ceramic fiber or to improve velocity resistance in which one edge of a blanket is lapped over an adjacent blanket edge by 4" to 12" and shares a common anchor stud and washer.

Paper: A roll product produced from ceramic fibers and organic binders on conventional paper-making machinery.

Parquet: A method of installing modular edge-grained forms of ceramic fiber so that the edge grain of one module is perpendicular to the edge grain of the adjacent modules.

Rigidizing: The practice of applying an inorganic hardening agent to the surface of ceramic fiber (by spray or brush) in order to improve its velocity resistance.

RCF: Refractory Ceramic Fiber.

Shingled Joint: A method of applying double layers of ceramic fiber blanket in such a way that half the width of each layer overlaps half the width of the adjacent layer.

Shot: A glassy material formed during fiberization.

Textile: Cloth, tape, sleeving, tubing, or other forms manufactured from ceramic fiber yarn.

Thermal Conductivity: The property of material to conduct heat - measured in Btu flow per hour through a square foot of area across one inch of thickness Btu•in/hr•ft²•F (w/m •C°).

Thermal Resistivity: The property of a material to resist the flow of heat; the reciprocal of thermal conductivity.

Thermal Shock: A failure mechanism wherein sudden changes in temperature bring sufficient thermal mechanical stress in a material to cause cracking or spalling. As a general rule, the thermal shock resistance of a material is greater as the strength and thermal conductivity of a material increase and as the thermal expansion and modulus of elasticity decrease.

Turbulent Flow: Fluid flow in which the velocity of a given stream of gas changes constantly both in magnitude and direction.

Vacuum Forming: A method of producing molded shapes and flat board by converting fibers into a slurry and vacuuming them onto a screen former.

Veneer: Layer of ceramic fiber in either blanket or module form which is attached to the hot face of a brick, module or monolithic lining.

Wallpaper Construction: The term used to describe a ceramic fiber lining construction technique where the blanket is installed on a wall like a roll of wallpaper.

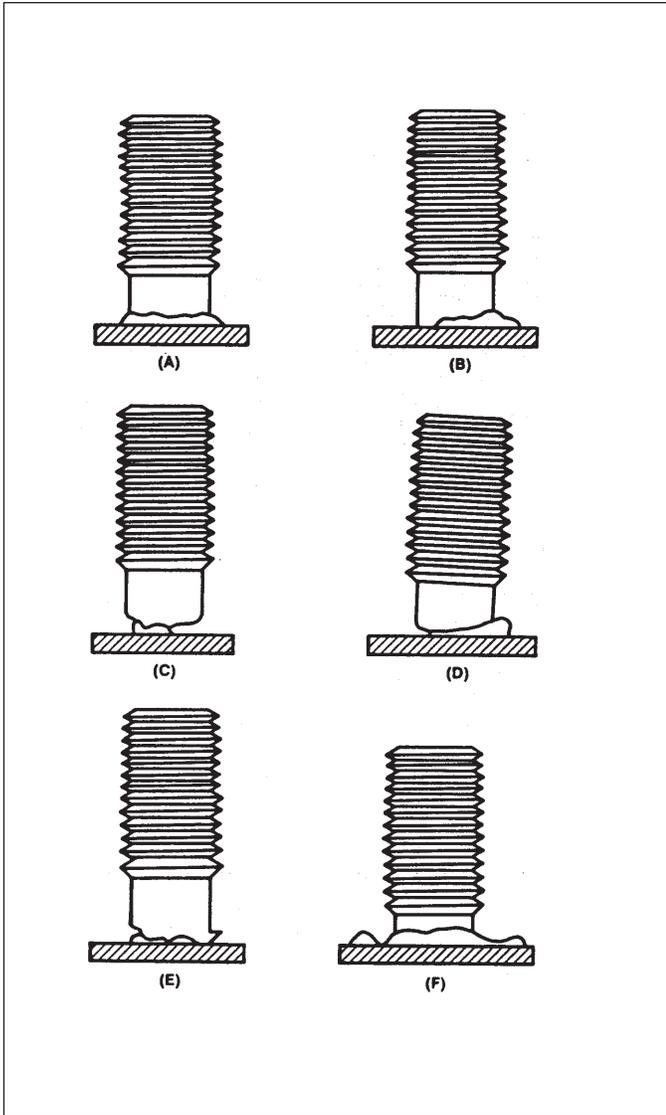

Figure 14 - Weld Inspection (Good and Bad Welds)

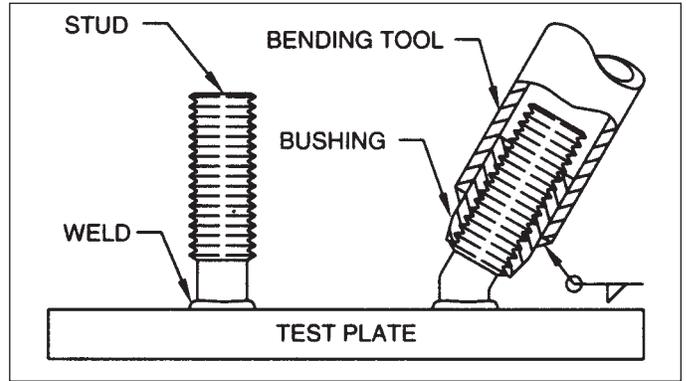

Figure 15 - Bend Test

The most common method for testing the welds is the bend test. This is carried out by striking the stud with a hammer or by using a bending tool such as a pipe (Figure 15). In the case of a good weld, the stud will break before the weld. In either case, the testing will damage the stud, so shoot the test studs on a separate plate or be prepared to grind smooth the area and reshoot.

As with any welding process, the operator should understand the process, properly maintain the equipment and follow proper safety precautions.
